```

Exercise 2

Q2.1

Since we want to know the effect of price on demands and prices are variables(regressors) which will not change across different choices, we shall use conditional logit model

Q2.2

```
#Download the data from two excel forms
M<-data.frame(read.csv("~/Desktop/613/hw3/product.csv",stringsAsFactors=FALSE))</pre>
N<-data.frame(read.csv("~/Desktop/613/hw3/demos.csv",stringsAsFactors=FALSE))
#Calculate X matrix and do normalization
Xprice<-M[,4:13]</pre>
Xnew < -t(matrix(rep(t(Xprice[,1]),each=10),nrow=10,ncol=4470))
Xpricenew<-Xprice-Xnew
# Construct a decision matrix named Ydumy to demonstrate all individuals' choices
Ydumy<-matrix(0,nrow=4470,ncol=10)
for (i in 1:10){
  Ydumy[,i]<-as.numeric(M$choice==i)
}
#Construct a likelihood funciton of the conditional logit model
Targetcondlogit<-function(par.,X.=Xpricenew,Ydumy.=Ydumy){</pre>
  # Construct a alfa matrix by using par.
  A0 < -matrix(0, nrow=4470, ncol=1)
  A1 < -matrix(par.[2], nrow=4470, ncol=1)
  A2 < -matrix(par.[3], nrow=4470, ncol=1)
  A3<-matrix(par.[4],nrow=4470,ncol=1)
 A4<-matrix(par.[5],nrow=4470,ncol=1)
  A5<-matrix(par.[6],nrow=4470,ncol=1)
  A6<-matrix(par.[7],nrow=4470,ncol=1)
  A7<-matrix(par.[8],nrow=4470,ncol=1)
  A8<-matrix(par.[9],nrow=4470,ncol=1)
  A9<-matrix(par.[10],nrow=4470,ncol=1)
  A<-as.matrix(data.frame(A0,A1,A2,A3,A4,A5,A6,A7,A8,A9))
  # Calculate V
  V < -X.*par.[1]+A
  # Calculate probability matrix
  Pd < -exp(V)
 Pn<-rowSums(Pd)
 P<-Pd/Pn
  P < -log(P)
  # Take out all the probabilities that are applied (be chosen) and calculate -likeli
hood of the conditional logit model
  test1<-P*Ydumy.
  likelihood log<--sum(test1)</pre>
  return(likelihood log)
}
#Do optimization
beta conditionlogit<-optim(par=par, Targetcondlogit)</pre>
beta condlogit<-as.matrix(beta conditionlogit$par)</pre>
#Print the outcome: beta, alfa1, alfa2, alfa3, alfa4, alfa5, alfa6, alfa7, alfa8, alfa9
print(beta condlogit)
```

```
##
               [,1]
## [1,] -6.3356644
##
   [2,] -0.7013063
## [3,] 1.0413609
##
   [4,] -1.3293418
##
   [5,] -2.3060072
   [6,] -3.3303433
##
   [7,] 0.2504691
##
##
   [8,] 1.8993582
##
   [9,] 2.5751385
## [10,] -3.4439153
```

```
# Write the data into excel form
write.csv(beta_condlogit,"~/Desktop/613/hw3/beta_condilogit.csv")
```

Question 2.3

Because beta is negative, which indicates that the higher the price it is, the less utility that an individual will have by choosing the product, and the less likely it is that an individual is going to choose the product.

alfa1, alfa3, alfa4, alfa5, alfa9 are all negative, which indicates that compared with the product 1 (PPk_Stk), product 2,4,5,6,10 (PBB_Stk,

PHse_Stk,PGen_Stk,PImp_Stk,PHse_Tub) are less preferred and thus are less likely to be chosen given the same price.

alfa2, alfa6,alfa7, alfa8, are all positive, which indicates that compare with the product 1 (PPk_Stk), product 3,7,8,9 (PFI_Stk,PSS_Tub,PPk_Tub,PFI_Tub) are more preferred and thus they are more likely to be chosen given the same price.

Exercise 3

Question 3.1

Since we are interested in the effect of family income on demand, and family income does change across alternatives, I think we shall choose multinomial logit model.

Question 3.2

```
#Download data from two excel forms
M<-data.frame(read.csv("~/Desktop/613/hw3/product.csv",stringsAsFactors=FALSE))</pre>
N<-data.frame(read.csv("~/Desktop/613/hw3/demos.csv",stringsAsFactors=FALSE))
#Merge two data frame to a new data frame and take out income variable as X variable
X < -M[, 2:13]
Y < -N[, 2:3]
Data3<-merge(X,Y,by.X="hhid",all.X=TRUE)</pre>
Xincome < -t(matrix(rep(t(Data3[,13]),each=10),nrow=10,ncol=4470))
#Construct a decision matrix named Ydumy
Ydumy<-matrix(0,nrow=4470,ncol=10)
for (i in 1:10){
     Ydumy[,i]<-as.numeric(Data3$choice==i)
#Construct the likelihood function of multinomial logit model
Target_multinomial<-function(par1.,X.=Xincome,Ydumy.=Ydumy){</pre>
     #Construct Vij matrix
     alfa<-matrix(rep(c(0,par1.[1:9]),each=4470),nrow=4470,ncol=10)
     beta<-matrix(rep(c(0,par1.[10:18]), each=4470), nrow=4470, ncol=10)
     V<-alfa+beta*X.
     #Construct a probability matrix
     Pn < -exp(V)
     Pd<-rowSums(Pn)

Question 3.3

Since

beta_1,beta_2,beta_4,beta_5,beta_6,beta_7,beta_8,beta_9 are all negative, it is indicated that compared with the product 1, the higher income a household has, the less likely it is for him to buy product 2,3,5,6,7,8,9,10.

Since all alfa_j (j=1,2,3,4,5,6,7,8,9) are negative, it is indicated that given an individual (given fixed income), compared with the product 1, all other products (product 2,product 3,product 4,product 5,product 6,product 7,product 8,product 9,product 10) are less preferred

Exercise 4

Question 4.1: Compute the marginal effect of the conditional logit model (Marginal Effect at Average Value)

```
#Import data from excel forms and merge data to a new form named Data3
M<-data.frame(read.csv("~/Desktop/613/hw3/product.csv", stringsAsFactors=FALSE))
N<-data.frame(read.csv("~/Desktop/613/hw3/demos.csv",stringsAsFactors=FALSE))
X < -M[, 2:13]
Y < -N[, 2:3]
Data3<-merge(X,Y,by.X="hhid",all.X=TRUE)</pre>
Dataq4<-as.matrix(apply(Data3,2,FUN = mean))</pre>
#Construct a matrix to place variable: price and do normalization
Xq4condlogit<-t(Dataq4[3:12])</pre>
Xq4condlogit1<-matrix(rep(Xq4condlogit[1,1],each=10),nrow=1,ncol=10)</pre>
Xq4condlogit<-Xq4condlogit-Xq4condlogit1</pre>
#Calcualte marginal effect of conditional logit modle by using a function
condmeq4<-function(par.,X.=Xq4condlogit){</pre>
  alfa<-matrix(c(0,par.[2:10]),nrow=1,ncol=10)
  #Construct the Vij matrix
  V<-X.*par.[1]+alfa
  #Calculate probability and get Probability matrix
  Pn < -exp(V)
  Pd<-rowSums(Pn)
  Ppre<-Pn/Pd
  #Calculate marginal effect
  P<-matrix(rep(Ppre,each=10),nrow=10,ncol=10)
  Pt < -t(P)
  I < -diag(10)
  me < -P*(I-Pt)*par.[1]
  return (me)
}
#Import beta and alfa j of exercise 2 from an excel form
beta conlogitq4<-read.csv("~/Desktop/613/hw3/beta condilogit.csv")
beta conlogq4<-c(beta conlogitq4[,2])
#Get marginal effect at average value of conditional logit modle
me conlogit<-condmeq4(beta conlogq4)</pre>
#Print the outcome
print(me_conlogit)
```

```

```

Interpret the marginal effect at average value:

It is easily found that in the marginal effect at average value matrix, the values in the diagonal are all negative, but other values are positive. This indicates that the increase in the corresponding component of the price variable for kth alternative increases the probability of the kth alternative and decrease the probability of the other alternatives

Question 4.2: Compute the marginal effect of multinomial logit model(Average Marginal Effect)

```
#Calculate marginal effect by using a function
multmeq4<-function(beta., X.=Xincomeq4){</pre>
  #Construct a probability matrix (4470*10)
  alfa<-matrix(rep(c(0,beta.[1:9]),each=4470),nrow=4470,ncol=10)
  beta < -matrix(rep(c(0,beta.[10:18]),each=4470),nrow=4470,ncol=10)
  #Calculate Vij matrix
  V<-alfa+beta*X.
  #Calculate the probability matrix
  Pn < -exp(V)
  Pd<-rowSums(Pn)
  P<-Pn/Pd
  #Construct a beta_bar matrix
  betatest<-as.matrix(rowSums(P*beta))
  beta bar<-t(matrix(rep(t(betatest),each=10),nrow=10,ncol=4470))
  #Calculate marginal effect of multinomial logit model
  betadiff<-beta-beta bar
  me<-P*betadiff</pre>
  return (me)
}
#Import beta j and alfa j of exercise 3 from an excel form
beta mullogita4<-read.csv("~/Desktop/613/hw3/beta multilogit.csv")
beta mullogq4<-c(beta mullogita4[,2])</pre>
memultq4<-multmeq4(beta mullogq4)</pre>
amemultq4 < -t(as.matrix(apply(memultq4, 2, FUN = mean)))
#Print the outcome: average marginal effect
print(amemultq4)
##

#Construct a matrix to place income variable

Xincomeq4 < -t(matrix(rep(t(Data3[,13]),each=10),nrow=10,ncol=4470))

Interpret the average marginal effect of multinomial logit modle

[1,] -0.001187125 -0.001050134 -0.00107676 -0.0009258742 -0.001440205

It is find that the average marginal effect of choice one and choice three on income is positive, and average marginal effects of all other choices on income are negative. It is indicated that the higher the income of an individual it is, the more likely he is to choose product 1 and product 4, the less likely he is to choose product 2,3,5,6,7,8,9,10.

Exercise 5

Questions 5.1

```
#Import data from two excel forms
